

Development & Application of a Multi-Scale Flow Field Analysis System for Complex Terrain

Ulrich Uhrner, Johannes Werhahn, Raphael
Reifeltshammer & Renate Forkel

Introduction

- For dispersion good representation of flow important at **local scale**
- **Initialisation & BC** still major challenge
 - **Complex terrain**
 - Catabatic conditions
- Typically only few wind measurements available
- **Use regional model for Init & BC**
 - optionally use available surface measurements

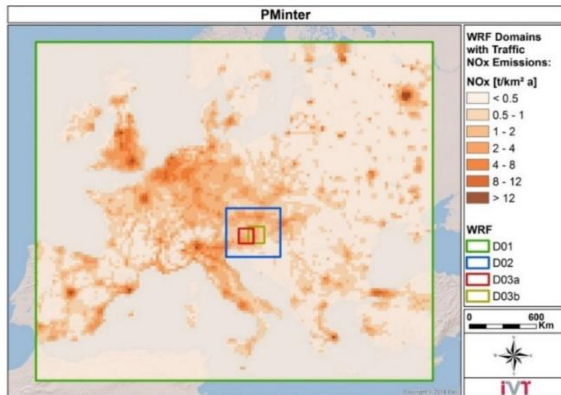

- Model & Approach
- Impact of model orography
- Data flow regional/local
- Results complex terrain
- Results alpine foreland
- Summary

regional e.g. WRF

- Global (ECMWF ERA-INTERIM)
- Multi-nesting $\Delta x, y$ 25/5/1 km
- smallest Domain 130 km x 142 km
-

local GRAMM

- SIMPLE algorithm (Patankar & Spalding, 1972)
- $\Delta x, y$ 50m – 300m
- Prognostic non-hydrostatic

58 km x 90 km
 $\Delta x, y$ 250m

January 2010: low WS & frequent Inversions – tricky!

Different model orography & complex terrain implications

Domain
140 km x 145 km
H asl processed at
1 km x 1 km

Local domain
58 km x 90 km
H asl processed at
250 m x 250 m

Different model orography & complex terrain implications

finer, detailed & ragged orography → implications on flow:

- steeper slopes → more drag
- vertical velocity (lift force, vortices)
- wind direction (drainage, vortices)

➤ Large difference in $\Delta x, y$ → strong impact on flow

Difference model orography

Problematic zone near model domain boundaries, - either

- „smart“ domain choice & smoothing/levelling off
- Create **hybrid orography transition zone**
 boundary: regional orography – core: local HR orography
 → may allow arbitrary domain choice

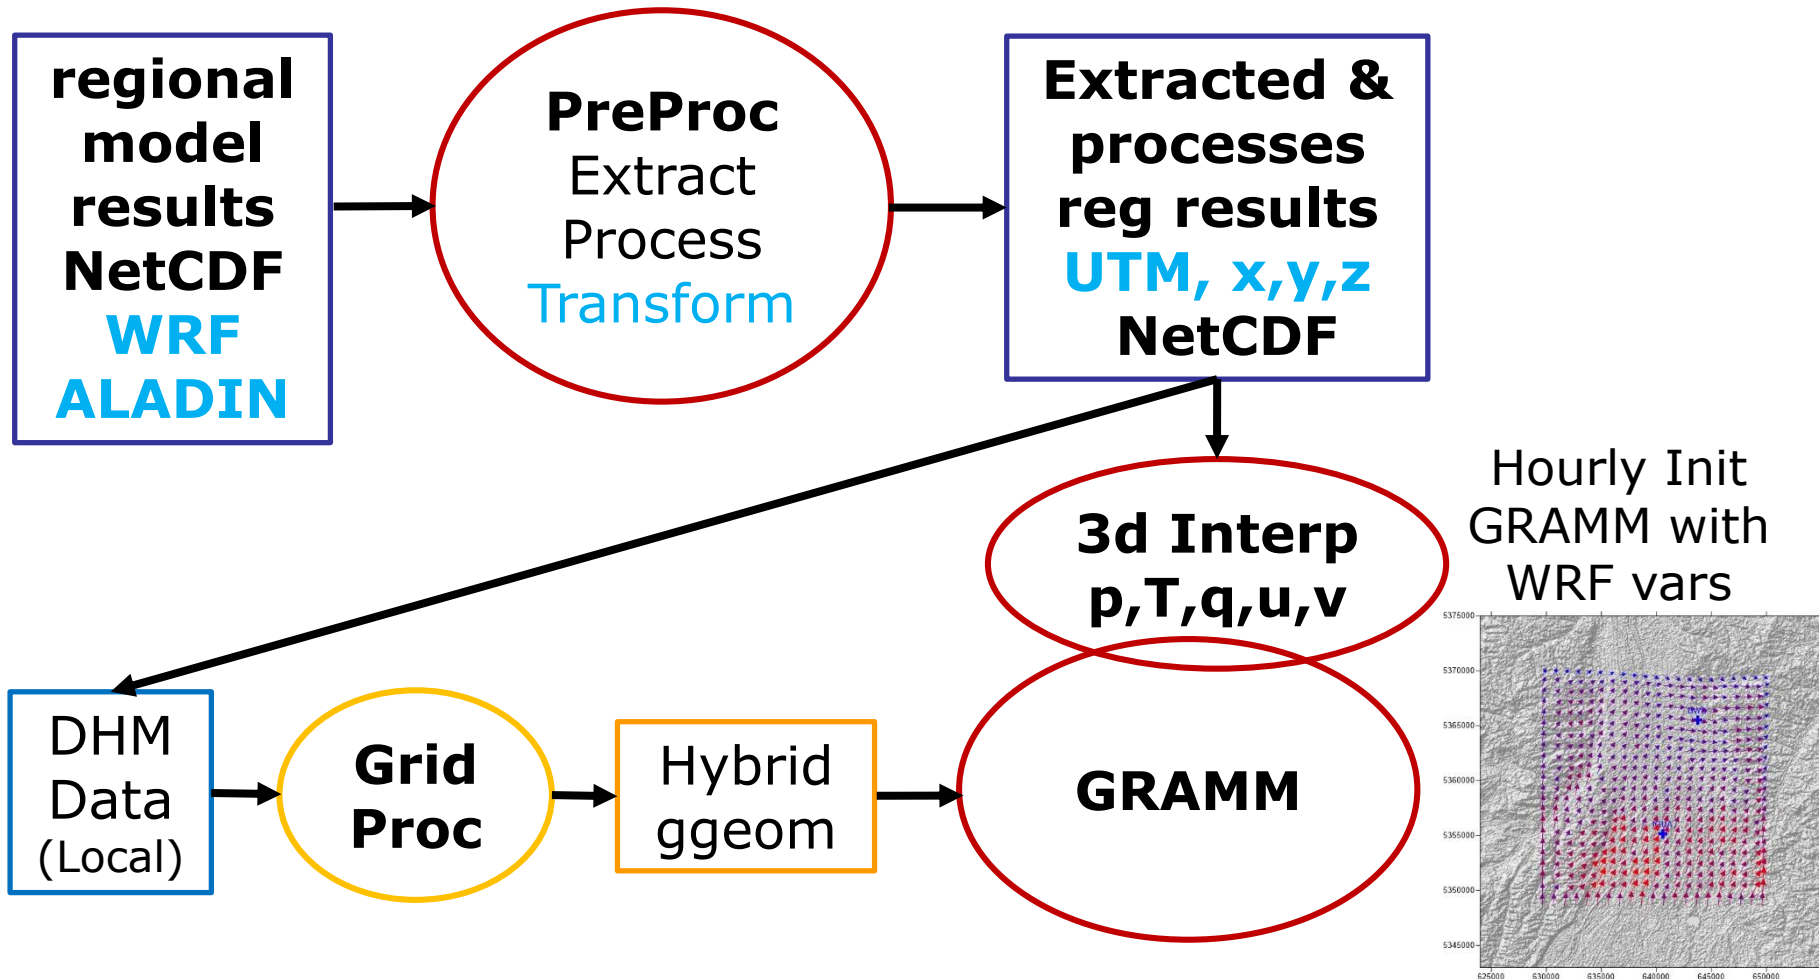

Dif Orogr
Local-Regional

**Transition
zone**

Data Flow regional-local & NetCDF

Common Data Format (NetCDF), machine independent, open data standard

Flow field WRF-GRAMM

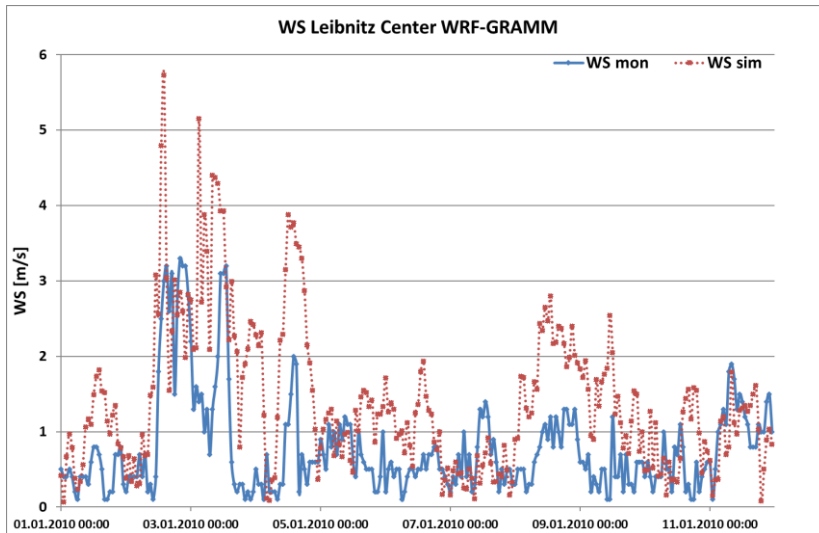

HARMO19

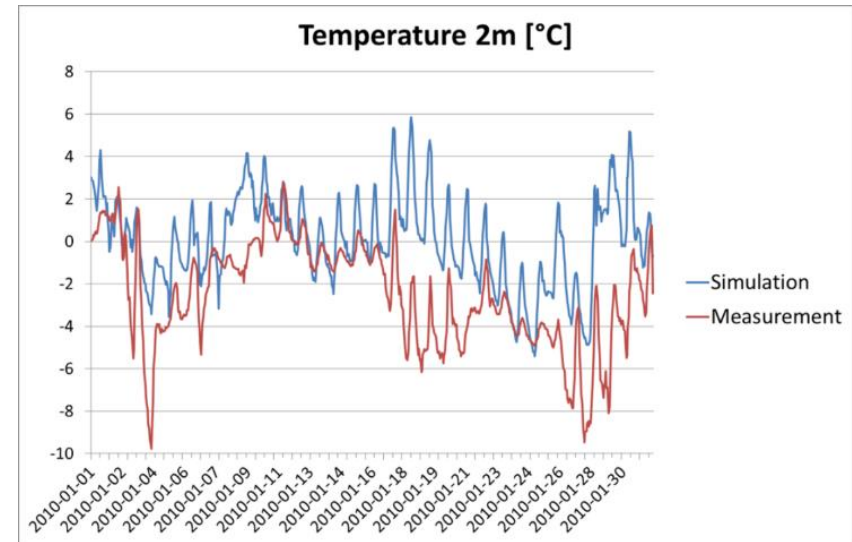

Bruges, 05.06.2019

Ulrich Uhrner

WS & Wdir WRF-GRAMM

By measurements modified initialisation

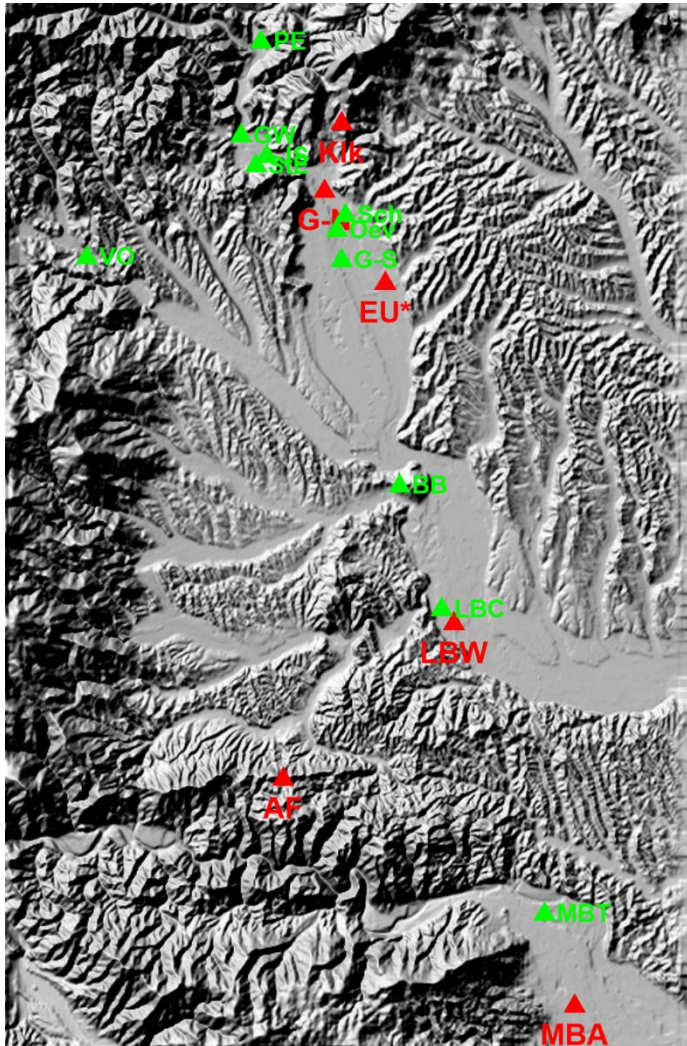

- Reg models substantial deficiencies in complex terrain, i.e. low WS conditions in valleys strong T inversions not captured
- Modified cond` initialisation using Wind & T sfc measurements

$$|(u_{sim} - u_{mon})/u_{mon}| > crit \quad \&\& \quad |(v_{sim} - v_{mon})/v_{mon}| > crit$$

$$WS \leq 0.8 \text{ m/s } crit = 1 \quad 0.8 \text{ m/s} < WS \leq 1.5 \text{ m/s } crit = 0.5$$

$$WS \geq 1.5 \text{ m/s } crit \text{ is set to } 0.25$$

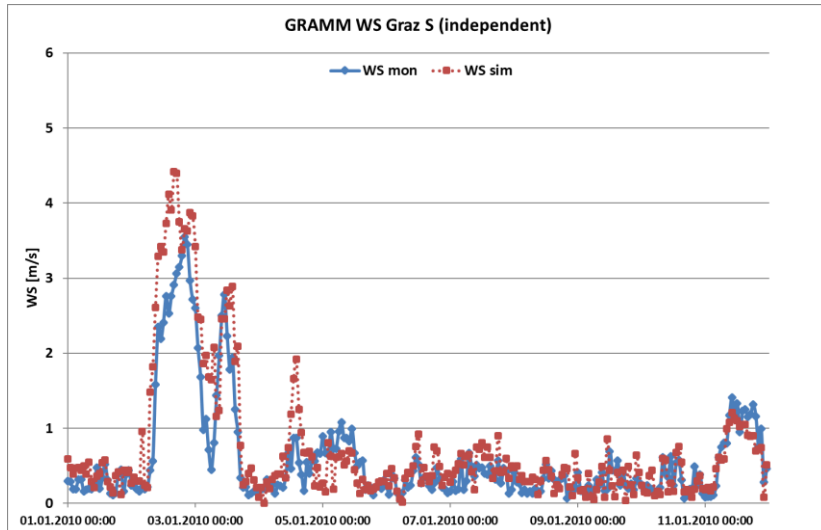

By measurements modified initialisation

- Vertical weighting profiles:
 near ground $W_{\text{mon}} = 1/W_{\text{RM}} = 0$
 at $H_{\text{max peak}}$ $W_{\text{mon}} = 0/W_{\text{RM}} = 1$

$$zwgt_{i,j,k} = 1 - \Delta z_{i,j,k} / (H_{\text{max peak}} - H_{\text{min}})$$
- 6 selected forcing stations
- Localized horiz Wgt (1/R crit)
- Correction for T_{sfc} & T-profile
- further stations used for independent validation

 $\Delta x, y = 100m$

Augsburg 19.09.-27.09.18

Summary

- Efficient WRF-GRAMM coupling implemented
- Overall, in complex terrain good representation of mountain and valley wind systems
- WRF-GRAMM reduced significantly excess momentum, improved representation of WS & WD
- modified initialisation using measurements - good results obtained (reanalysis mode)
- In hilly terrain (Augsburg) better WRF performance
→ very good WRF-GRAMM results
