16th International Conference on Harmonisation within Atmospheric Dispersion Modelling for Regulatory Purposes

Overview

- 1 Motivation
- 2 Objectives
- 3 Methods
- 4 Model
- 5 Results
- 6 Conclusion

Why uncertainty and sensitivity analysis?

- Role of models has changed – need for uncertainty and sensitivity analysis

Why uncertainty and sensitivity analysis?

- Role of models has changed – need for uncertainty and sensitivity analysis
- Guide research directions

Why uncertainty and sensitivity analysis?

- Role of models has changed – need for uncertainty and sensitivity analysis
- Guide research directions
- Improve scientific communication – transparency

Why uncertainty and sensitivity analysis?

- Role of models has changed – need for uncertainty and sensitivity analysis
- Guide research directions
- Improve scientific communication – transparency
- Has not been performed for air quality models before

1 Motivation

Only little tradition for uncertainty and sensitivity analysis within atmospheric dispersion modelling.

Possible explanations:

- Is computational intensive

1 Motivation

Only little tradition for uncertainty and sensitivity analysis within atmospheric dispersion modelling.

Possible explanations:

- Is computational intensive
- Originated in other branches of science (ecological modelling, econometrics, engineering etc.)

1 Motivation

Only little tradition for uncertainty and sensitivity analysis within atmospheric dispersion modelling.

Possible explanations:

- Is computational intensive
- Originated in other branches of science (ecological modelling, econometrics, engineering etc.)
- Lack of demonstration of feasibility and advantage of approach

Methodology of choice: The iterative parameter estimation and identifiability analysis of Brun et al. (2001). It has been widely applied in other branches of science.

Aim: To analyse the applicability of applying the parameter estimation and identifiability analysis methodology to a model within atmospheric science, in this case the Operational Street Pollution Model (OSPMTM).

The method consists of ten steps (Brun et al., 2002):

- 1 Define model

3 Methods

The method consists of ten steps (Brun et al., 2002):

- 1 Define model
- 2 Specify experimental layout

3 Methods

The method consists of ten steps (Brun et al., 2002):

- 1 Define model
- 2 Specify experimental layout
- 3 Prior analysis

3 Methods

The method consists of ten steps (Brun et al., 2002):

- 1 Define model
- 2 Specify experimental layout
- 3 Prior analysis
- 4 Calculate model output

3 Methods

The method consists of ten steps (Brun et al., 2002):

- 1 Define model
- 2 Specify experimental layout
- 3 Prior analysis
- 4 Calculate model output
- 5 Compute sensitivities

The method consists of ten steps (Brun et al., 2002):

- 1 Define model
- 2 Specify experimental layout
- 3 Prior analysis
- 4 Calculate model output
- 5 Compute sensitivities
- 6 Produce parameter importance ranking

The method consists of ten steps (Brun et al., 2002):

- 1 Define model
- 2 Specify experimental layout
- 3 Prior analysis
- 4 Calculate model output
- 5 Compute sensitivities
- 6 Produce parameter importance ranking
- 7 Assess identifiability of parameter subsets

The method consists of ten steps (Brun et al., 2002):

- 1 Define model
- 2 Specify experimental layout
- 3 Prior analysis
- 4 Calculate model output
- 5 Compute sensitivities
- 6 Produce parameter importance ranking
- 7 Assess identifiability of parameter subsets
- 8 Choose parameter subsets for manual tuning or parameter estimation

3 Methods

The method consists of ten steps (Brun et al., 2002):

- 1 Define model
 - 2 Specify experimental layout
 - 3 Prior analysis
 - 4 Calculate model output
 - 5 Compute sensitivities
 - 6 Produce parameter importance ranking
 - 7 Assess identifiability of parameter subsets
 - 8 Choose parameter subsets for manual tuning or parameter estimation
 - 9 Tune selected parameters manually or perform parameter estimation
- Iterate until convergence**

3 Methods

The method consists of ten steps (Brun et al., 2002):

- 1 Define model
- 2 Specify experimental layout
- 3 Prior analysis
- 4 Calculate model output
- 5 Compute sensitivities
- 6 Produce parameter importance ranking
- 7 Assess identifiability of parameter subsets
- 8 Choose parameter subsets for manual tuning or parameter estimation
- 9 Tune selected parameters manually or perform parameter estimation
- 10 Explore potential bias problems

Iterate until convergence

Identifiability analysis: Search for parameters identifiable from data

For a parameter to be identifiable:

- The model have to be sensitive to small changes in the parameter
 $\left(\left| \frac{\partial f(u, \theta)}{\partial \theta} \right| \gg 0 \right)$
- Only small compensation effects in the model output. Analysed via linear dependency of the sensitivity matrix.

Parameter estimation: Estimation of parameters from data

- Used least-squares minimization criterium
- Weighted to balance species

Model input:

- Species: NO_x and NO_2
- Years: 1994–2010
- Five streets in major cities in Denmark
- Meteorology and urban background concentration from rooftop stations
- Measurements from Ellermann et al. (2013)
- Two data splitting approaches: DUPLEX and Seasonal

4 The Operational Street Pollution Model (OSPM™)

Roof level wind

5 Results

Local sensitivity analysis

Relative sensitivity for NO_x

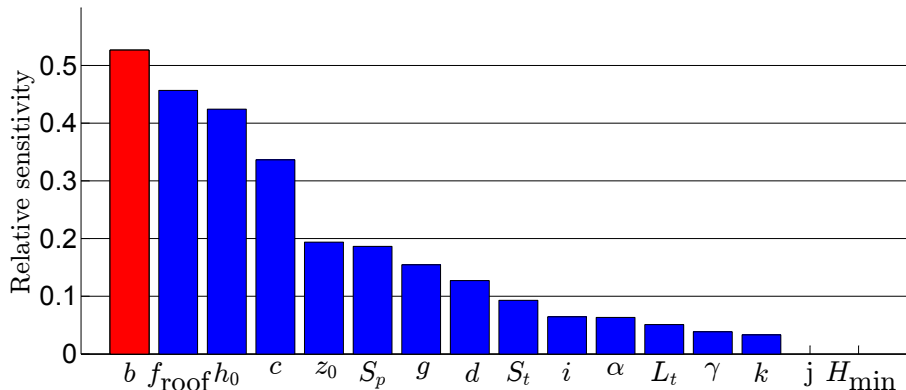

Distinct trend in sensitive and non-sensitive parameters – dependent on parameter values

5 Results

Local sensitivity analysis

Relative sensitivity for NO_x

Scale-factor for traffic-produced turbulence

5 Results

Local sensitivity analysis

Relative sensitivity for NO_x

$$f_{\text{roof}} = \frac{u_{\text{mast}}}{u_{\text{roof}}}$$

5 Results

Local sensitivity analysis

Relative sensitivity for NO_x

Slope of emission plume

In general: More sensitivity \rightarrow less uncertainty

5 Results

Validation of estimated parameters – Statistics

Approximately homogeneous correlation before and after

5 Results

Validation of estimated parameters – Statistics

Approximately homogeneous correlation before and after

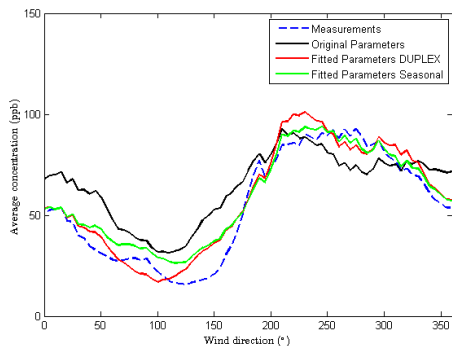

More homogeneous and reduced fractional bias after fit

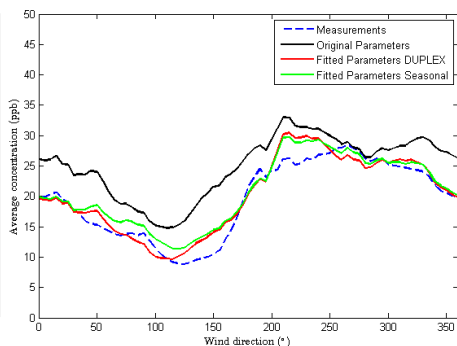

5 Results

Validation of estimated parameters – Wind direction

Wind direction plot: Albanigade, Odense

(a) NO_x

(b) NO_2

5 Results

Validation of estimated parameters – Diurnal Variation

Diurnal average plot: Albanigade, Odense

(c) NO_x

(d) NO₂

The methodology:

- Successfully estimates a set of parameters with better performance statistics compared to the original model parameters

The methodology:

- Successfully estimates a set of parameters with better performance statistics compared to the original model parameters
- Balances the fractional bias among the individual streets and species

The methodology:

- Successfully estimates a set of parameters with better performance statistics compared to the original model parameters
- Balances the fractional bias among the individual streets and species
- Converts other types of uncertainty into parameter uncertainty

The methodology:

- Successfully estimates a set of parameters with better performance statistics compared to the original model parameters
- Balances the fractional bias among the individual streets and species
- Converts other types of uncertainty into parameter uncertainty
- Have significantly increased the transparency about the model performance and model uncertainty

The methodology:

- Successfully estimates a set of parameters with better performance statistics compared to the original model parameters
- Balances the fractional bias among the individual streets and species
- Converts other types of uncertainty into parameter uncertainty
- Have significantly increased the transparency about the model performance and model uncertainty

Other experiences:

- The 95% confidence intervals underestimates uncertainties
