HARMO 18, Bologna, Italy, 9-12 October 2017

# JR II Cloud, Trial 5, looking toward south (upwind) 0.5 sec after release starts

Side to side dimension of obstacle array = 100 m

# Jack Rabbit II

- Follows JR I (10 trials in 2010), releasing 1 or 2 tons of pressurized liquefied chlorine or anhydrous ammonia. Mostly light winds, downward release into artificial 2 m deep by 25 m radius depression. C observations to 500 m.
- JR II 2015 – 5 trials, releasing 5 to 9 tons. Moderate winds, downward release in middle of mock urban array. Downwind C observations to 11 km, and inside some buildings.
- JR II 2016 – 4 trials, releasing 10 to 20 tons over flat desert surface (same set-up as 2015 but with mock urban array removed). Trials 6 and 9 downwards, trial 7 45° downwards, trial 8 up.

# JR II C Samplers on 2, 5, and 11 km arcs

Azimuth of grid centerline: 345 deg

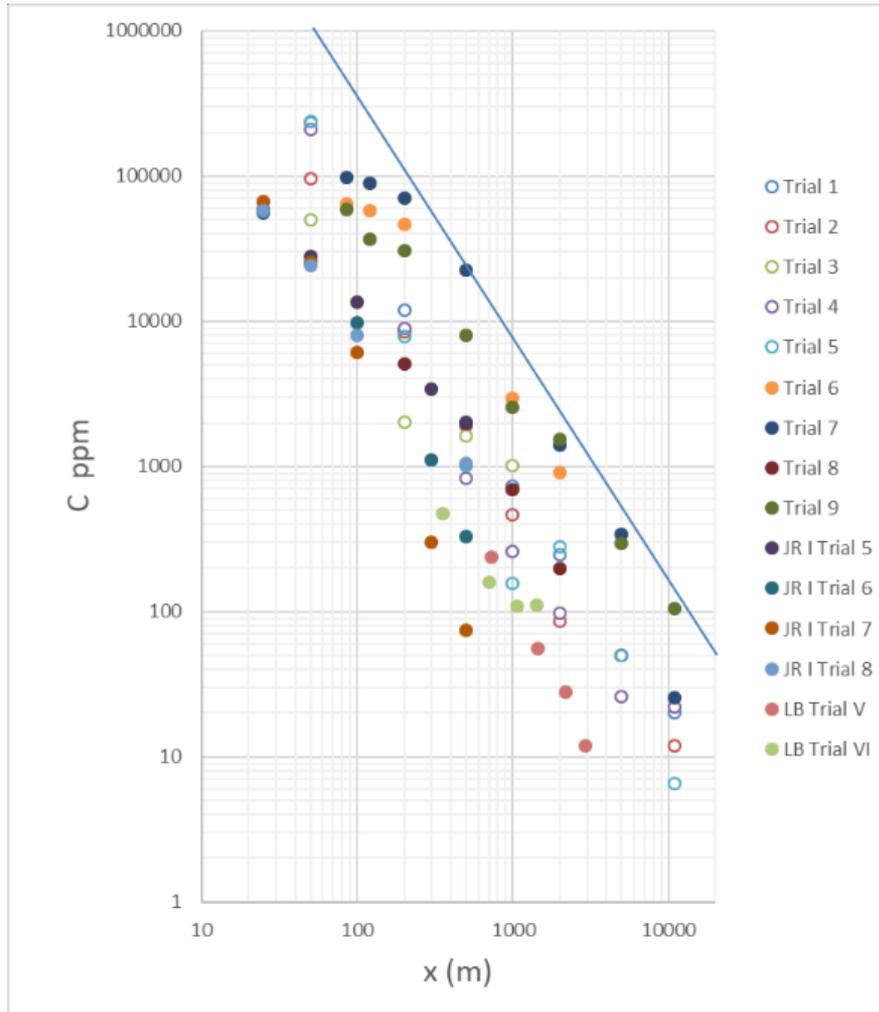

# JR II Trial 2, 4.3 sec after the release starts

# Part 1 of paper – Plots of C and Cu/Q versus distance x

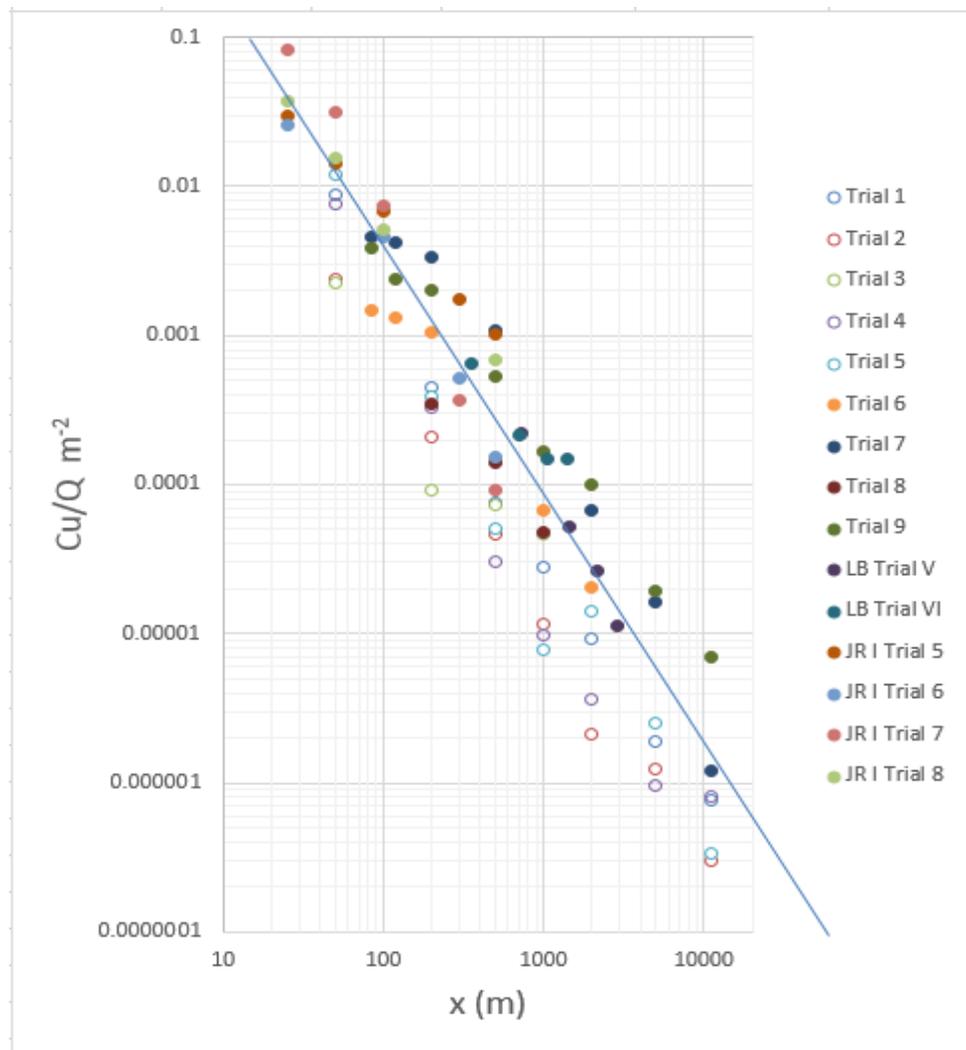

- C is arc max 1-3 s average concentration; u is 2 m wind speed, Q is mass emission rate
- For emergency response guidance, a plot of C vs x combined for all release trials shows what to expect from release of 1 to 20 tons of chlorine
- Dimensional analysis should allow scatter to be reduced. Thus  $Cu/Q$  vs  $x$ .
- Fit line to observed  $Cu/Q$  vs  $x$  plot. It is found that  $Cu/Q$  is proportional to  $x^{-5/3}$

# Arc max C (in ppm) versus x for Lyme Bay (LB), Jack Rabbit I (JR I), and Jack Rabbit II (Trials 1 – 9)

The straight line represents the  $-5/3$  power law that best fits the max C point at the various x

# Arc max Cu/Q versus x for Lyme Bay (LB), Jack Rabbit I (JR I), and Jack Rabbit II (Trials 1 – 9)

The straight line represents the relation  $Cu/Q = 8.5x^{-5/3}$ , where  $Cu/Q$  has units  $m^{-2}$  and  $x$  has units  $m$

# Comments on Plot of $Cu/Q$ vs $x$

- Normalization with  $Q/u$  brought the Lyme Bay, JR I and JR II 2016 points closer together (reduced the scatter seen in the  $C$  vs  $x$  plot)
- However, the JR II 2015 points (where there was a mock urban obstacle array at  $x < 100$  m) were not moved much closer to the others and now are the “low values” on the plots
- The mock urban obstacles were seen to visibly enhance mixing and thus there may be an “initial mixing” effect that reduces concentrations over the whole sampling array

## Part 2 of paper - Vertical dense jet in Trial 8 (hole at top of tank)

- The dense jet rises up about 40 m (plume centroid height), then touches down to the ground at a distance of about 60 m
- Compare maximum rise and touchdown distance with Hoot et al (1973) analytical formulas

**Trial 8 dense plume about 30 s after release.  
Distance from the source to the red obstacle  
is about 85 m**

# Hoot, Meroney, and Peterka (1973)

Analyzed dense plume observations from many experiments in their wind tunnel. Came up with simple analytical formulas based on fundamental science

Plume rise  $\Delta h$  above source:

$$\Delta h/2R_o = 1.32 (w_o/u)^{1/3} (\rho_o/\rho_a) (w_o^2/(2R_o g'))^{1/3}$$

where  $g' = g(\rho_o - \rho_a)/\rho_o$ ;  $g$  is acceleration of gravity,  $\rho_a$  is ambient air density,  $u$  is wind speed, and  $\rho_o$ ,  $R_o$ , and  $w_o$  are initial plume density, radius and vertical velocity after depressurization.

# Hoot, Meroney, and Peterka (1973)

## slide 2

Plume touchdown distance  $x_g$  downwind:

$$x_g/2R_o = w_o u / (2R_o g') + 0.56 \{ (\Delta h / 2R_o)^3 * \\ ((2 + h_s / \Delta h)^3 - 1) u^3 / (2R_o w_o g_a') \}^{1/2}$$

where  $g_a' = g(\rho_o - \rho_a) / \rho_a$  and  $h_s$  is elevation of the stack or vent opening above the ground.

# Inputs to Hoot et al. formula

- $Q = 79 \text{ kg/s}$
- $T = -34 \text{ C}$  (chlorine boiling point)
- 20 % of mass released flashes (to gas). The rest is small aerosol drops. Assume effective initial density  $\rho_0$  is  $12.5 \text{ kg/m}^3$ .
- Sensitivity study with initial vertical velocity  $w_0$  of  $206 \text{ m/s}$  (sonic) and  $50 \text{ m/s}$ . These imply initial radius  $R_0$  of  $0.1$  and  $0.2 \text{ m}$ .

# Results of Hoot et al. formula

- For initial vertical velocity  $w_0$  of 206 m/s (sonic) and initial radius  $R_0$  of 0.1 m, plume rise  $\Delta h$  is 92 m and touchdown distance  $x_g$  is 100 m
- For initial vertical velocity  $w_0$  of 50 m/s (sonic) and initial radius  $R_0$  of 0.2 m, plume rise  $\Delta h$  is 36 m and touchdown distance  $x_g$  is 39 m
- These two predictions roughly bracket the observed values

# Conclusions

- The two types of initial analysis described above demonstrate that the JR II data follow expected scientific relations regarding variations of concentrations with downwind distance, and rise of dense plumes.
- As with all analysis of environmental data, there is much scatter.
