# THE FUNDAMENTAL QUESTION

---

Can RANS CFD Models 'predict' individual exposure over any exposure times (especially the short ones) ?

11<sup>th</sup> Conference on Harmonization within  
Atmospheric Dispersion Modeling for  
Regulatory Purposes  
July 2-5, 2007  
Cambridge, UK

# THE PROBLEM

---

- A hazardous substance is released in the atmosphere at a constant release rate at a certain point for a certain time
- The turbulent flow field is assumed stationary for the time of the release
- The precise (instantaneous) flow conditions of the time of the release are not known (by definition)

# THE TOOL

---

- A RANS – CFD model able to predict at all positions the
  - the mean concentration
  - the concentration variance
  - the time scale of turbulence

# Individual exposure estimation

---

- Individual exposure over  $\Delta\tau$ :

$$D(\Delta\tau) = \int_0^{\Delta\tau} C_{real}(t) \cdot dt \leq \left[ \int_0^{\Delta\tau} C_{stationary}(t) \cdot dt \right]_{\max} = D_{\max}(\Delta\tau)$$

- Maximum Individual Exposure

$$D_{\max}(\Delta\tau) = \Delta\tau \cdot C_{\max}(\Delta\tau) \quad C_{\max}(\Delta\tau) = \frac{1}{\Delta\tau} \left[ \int_0^{\Delta\tau} C_{stationary}(t) \cdot dt \right]_{\max}$$

$C_{\max}(\Delta\tau)$  the peak time-averaged concentration

# The peak time averaged concentration

---

- Bartzis et al (2007)

$$\frac{C_{\max}(\Delta\tau)}{\bar{C}} = f\left(I, \frac{\Delta\tau}{T_L}\right) \quad I = \frac{\sigma_C^2}{\bar{C}^2}$$

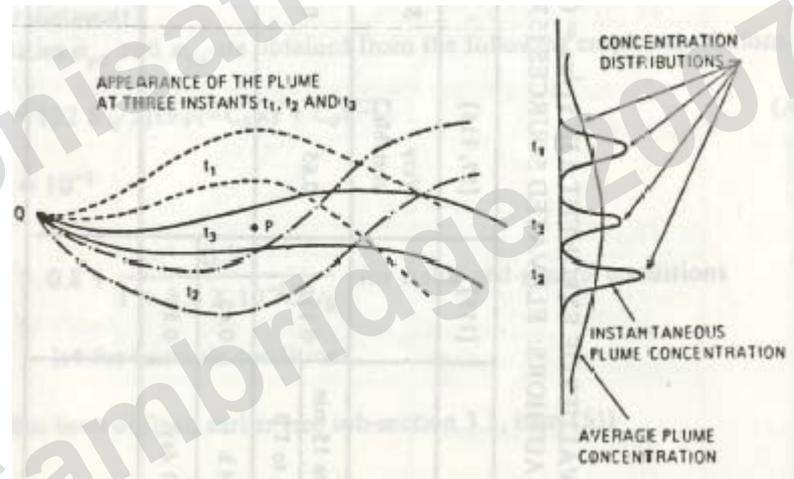

- The first correlation

$$\frac{C_{\max}(\Delta\tau)}{\bar{C}} = 1 + 1.5 \cdot I \cdot \left(\frac{\Delta\tau}{T_L}\right)^{-0.3}$$

# The Application: The FLADIS T16 field Experiment

---

## **Ammonia flashing near ground release**

- Release rate 0.27 kg/s
- Jet direction: horizontal
- Release duration 20 min
- Average wind speed at 10 m 4.4 m/s
- Near neutral conditions
- Ambient temperature 16 Celcius
- Relative humidity 62 %

# Experimental site – sensor positions

Cambridge, UK

# The model ADREA

---

- **Mesoscale/local scale**
- Stable/unstable ambient conditions
- One equation and two equation turbulence modeling
- Induced turbulence from moving objects (e.g. vehicles)
- One (dense/buoyant) pollutant
- 3-D RANS finite volume, transient
  - one/two phase release and dispersion
  - instantaneous/continuous releases
  - jets of arbitrary orientation (e.g. pipe exhaust, pipe/tank rupture etc)
- N passive substances reactive or not
  - CBM – IV gas chemistry (up to 36 species)
  - radioactivity
  - moist atmosphere (dispersion on gas and water phase in the atmosphere)

# The Conclusions

---

- The present work represent the first attempt to estimate peak time averaged mean concentrations utilizing the RANS CFD models.
- The model results comparisons with the FLADIS T16 ammonia flashing release experiment are quite encouraging.
- The models will require in the future to be more refined in estimating concentration variance and turbulent integral scales.

# The Final Conclusion

---

## Question

Can RANS CFD Models 'predict' individual exposure over any exposure times (especially the short ones) ?

## Answer

Yes . We need RANS CFD Models reliable in predicting mean concentration, concentration variance and turbulent time scales
