---

# Outline

---

- ◆ Introduction
- ◆ Previous work
- ◆ Lagrangian dispersion model
- ◆ Eulerian chemical scheme
- ◆ Treating the background ( $O_3$ ) concentration
- ◆ Preliminary test on a laboratory experiment
- ◆ Real case application
- ◆ Results and conclusion

# Introduction

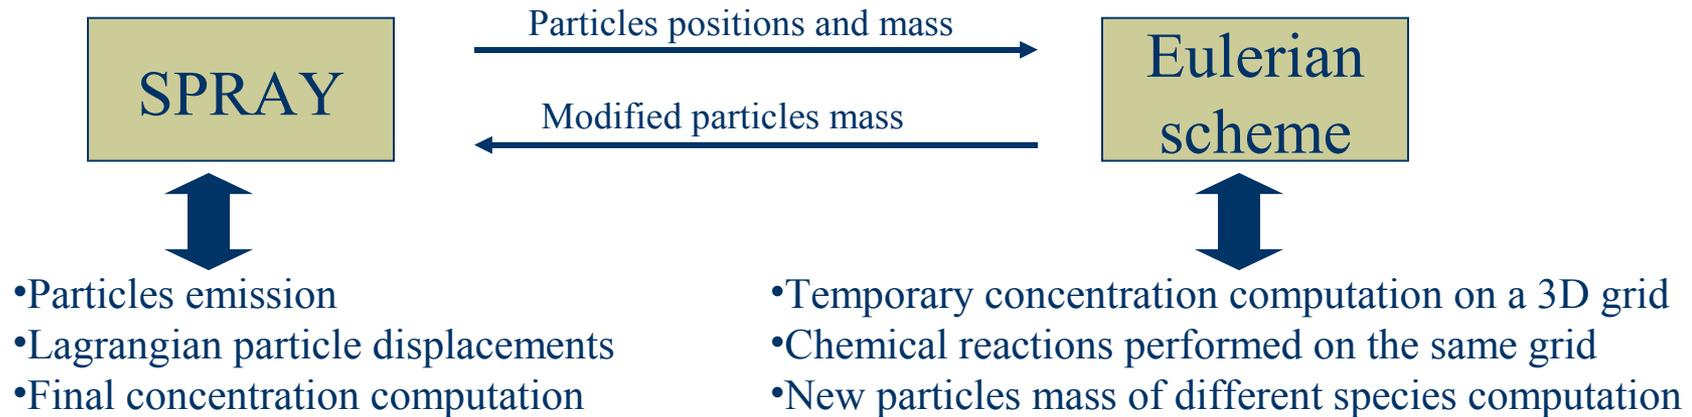

- ◆ Needs of estimating plume secondary pollutants like NO<sub>2</sub> for regulatory purposes
- ◆ Estimating short term non-equilibrium concentration in a plume with chemical reactions
- ◆ The lagrangian particle model is particularly suitable to simulate the dispersion at the small scale
- ◆ Two critical point: 1) how to simulate the background concentrations (how many particles); 2) how to simulate chemical reactions (eulerian scheme)
- ◆ In this work we have applied the model to a case in real atmosphere evaluating the dispersion of pollutants released by a power plant located in the North of Italy
- ◆ the model considers the photolysis of NO<sub>2</sub> due to solar radiation

# Previous work

- ◆ This is the prosecution of the work presented at the Harmo 11 conference
- ◆ We have presented an application of a lagrangian particle model with chemical reactions to a wind tunnel experiment
- ◆ The model was able to estimate a secondary pollutant like  $\text{NO}_2$  due to the only oxidation reaction:  $\text{NO} + \text{O}_3 \xrightarrow{k} \text{NO}_2 + \text{O}_2$
- ◆ The average concentrations were computed in a finite volume in an eulerian frame using a fixed grid
- ◆ The background  $\text{O}_3$  concentration filling the whole domain has been simulated by using the “deficit” method
- ◆ The model was validated against a wind tunnel data-set

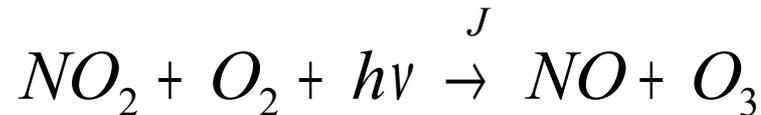

# Model Scheme

- ◆ The Eulerian model is included inside the lagrangian model, SPRAY, following the simple scheme:

# Algorithm for chemical reactions

- ◆ The set of chemical reactions considered is:

- ◆ The chemical kinetic follows:

$$\frac{\partial c_{NO}}{\partial t} = \frac{\partial c_{O_3}}{\partial t} = - \frac{\partial c_{NO_2}}{\partial t} = -k \cdot c_{NO} \cdot c_{O_3} + j \cdot c_{NO_2}$$

- ◆  $k$  depends on temperature and is around  $0.4 \text{ ppm}^{-1}\text{sec}^{-1}$  while  $J$  depends on solar radiation and ranges between 0 during the night and  $0.4 \text{ min}^{-1}$  in the full sunlight
- ◆ the  $O_2$  concentrations are neglected because this substance is always present in excess and his variation in time and space does not influence the kinetic  $J$  of the reaction

# Algorithm for chemical reactions

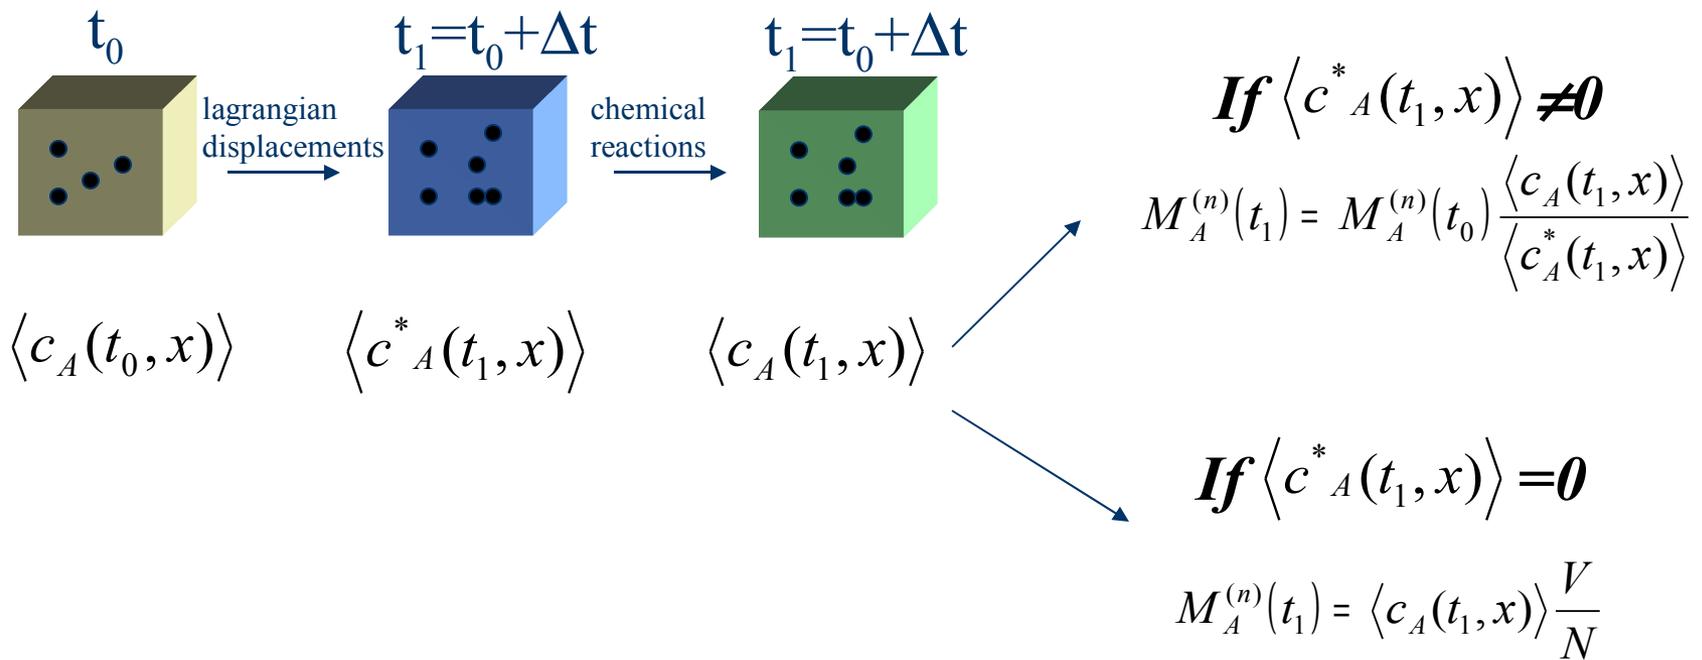

- ◆ Extension of the Chock and Winkler (1994a, 1994b) scheme
- ◆  $\mathbf{C}_{\text{NO,NO}_2,\text{O}_3}(\mathbf{x},t_0)$  is the concentration at the time  $t_0$
- ◆ After the turbulent displacements we have at the time  $t_1=t_0+\Delta t$ ,  
 $\mathbf{C}_{\text{NO,NO}_2,\text{O}_3}^*(\mathbf{x},t_1)$
- ◆ After the chemical reactions we have  $\mathbf{C}_{\text{NO,NO}_2,\text{O}_3}(\mathbf{x},t_1)$  from the following  
:

$$\langle c_{\text{NO}}(\mathbf{x}_j, t_1) \rangle = \langle c_{\text{NO}}^*(\mathbf{x}_j, t_1) \rangle - k\Delta t \langle c_{\text{NO}}^*(\mathbf{x}_j, t_1) \rangle \langle c_{\text{O}_3}^*(\mathbf{x}_j, t_1) \rangle + j\Delta t \langle c_{\text{NO}_2}^*(\mathbf{x}_j, t_1) \rangle$$

$$\langle c_{\text{NO}_2}(\mathbf{x}_j, t_1) \rangle = \langle c_{\text{NO}_2}^*(\mathbf{x}_j, t_1) \rangle + k\Delta t \langle c_{\text{NO}}^*(\mathbf{x}_j, t_1) \rangle \langle c_{\text{O}_3}^*(\mathbf{x}_j, t_1) \rangle - j\Delta t \langle c_{\text{NO}_2}^*(\mathbf{x}_j, t_1) \rangle$$

$$\langle c_{\text{O}_3}(\mathbf{x}_j, t_1) \rangle = \langle c_{\text{O}_3}^*(\mathbf{x}_j, t_1) \rangle - k\Delta t \langle c_{\text{NO}}^*(\mathbf{x}_j, t_1) \rangle \langle c_{\text{O}_3}^*(\mathbf{x}_j, t_1) \rangle + j\Delta t \langle c_{\text{NO}_2}^*(\mathbf{x}_j, t_1) \rangle$$

# Algorithm for chemical reactions: particles mass

# Background O<sub>3</sub> simulation

- ◆ Treating background species as static fields (as O<sub>2</sub>) is not a reasonable approximation in the case of O<sub>3</sub>
- ◆ O<sub>3</sub> concentration variation inside the plume need to be taken into account (Hegg et al. 1977).
- ◆ The changes of the O<sub>3</sub> background concentration occur only in presence of NO<sub>x</sub>, hence outside the plume, O<sub>3</sub> concentration remains constant (well mixed condition)
- ◆ It is not useful simulating the diffusion where NO is absent

# A new scalar: “deficit”

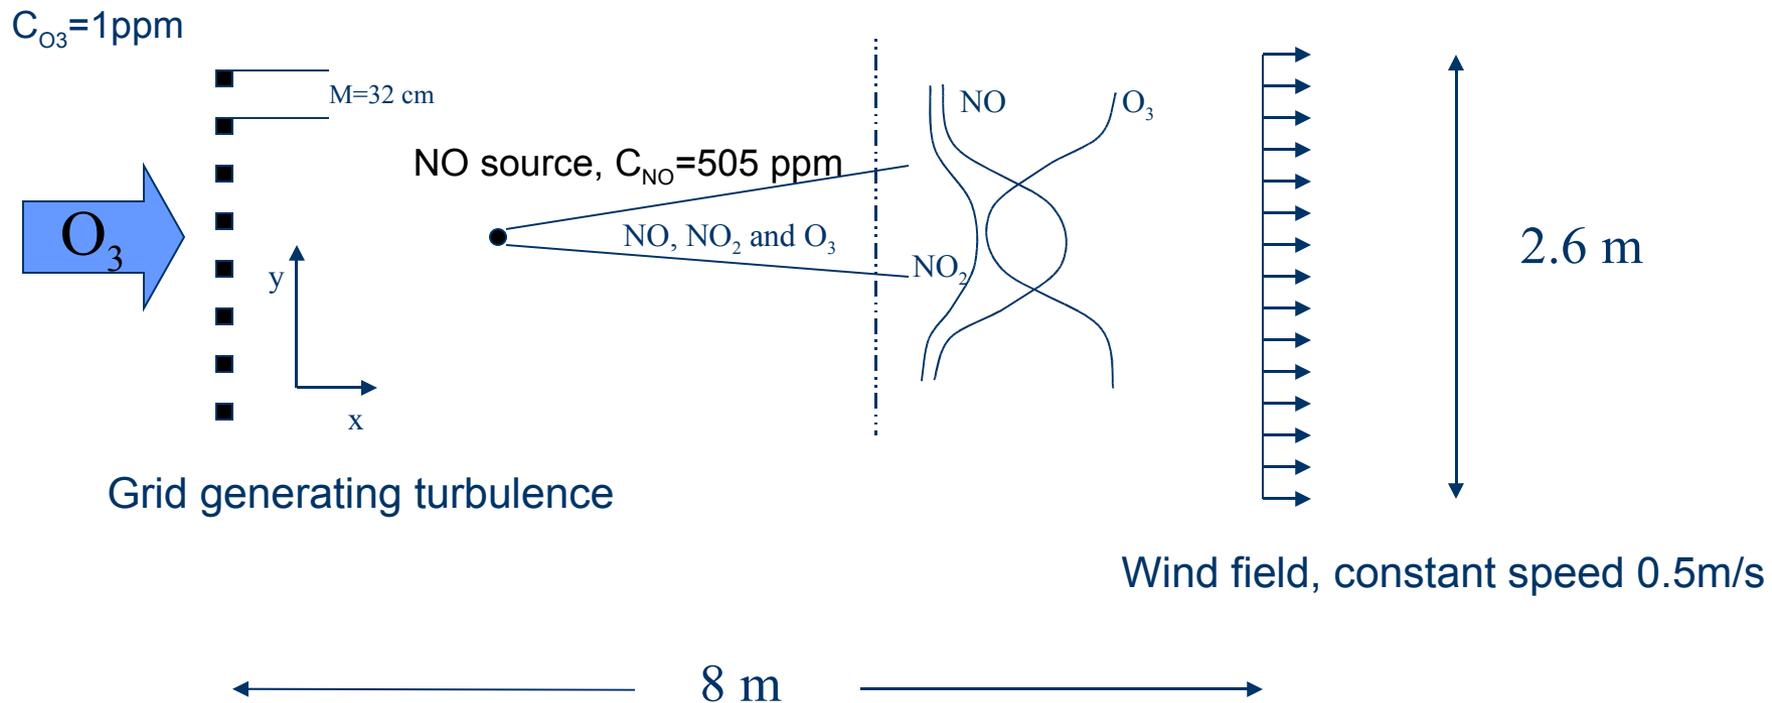

- ◆ The following new scalar is introduced:

$$C_{O_3\text{deficit}} = C_{O_3\text{back}} - C_{O_3}$$

where  $C_{O_3\text{back}}$  is the background homogeneous concentration value

- ◆ Every emitted particle carries a “deficit” of concentration
- ◆ The scalar  $C_{O_3\text{deficit}}$  is released only by the point source together with NO requiring no more particles than those of the plume
- ◆ The actual  $C_{O_3}$  is computed before the chemical reaction, therefore the chemical algorithm remains unchanged

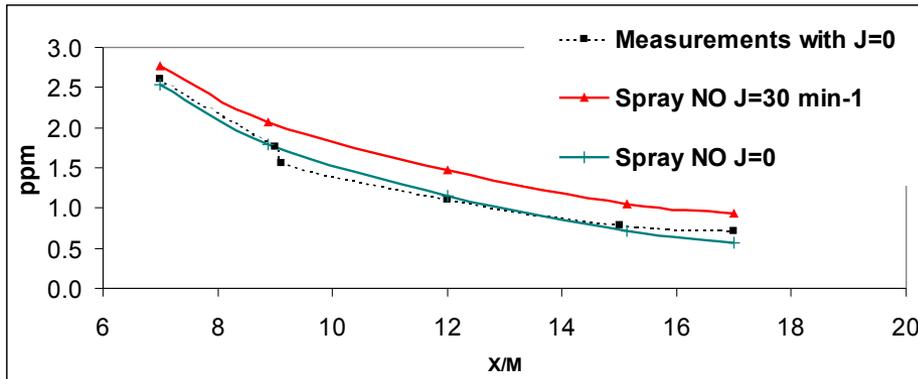

# Preliminary qualitative comparison

Wind tunnel experiment: Bilger et al.1996

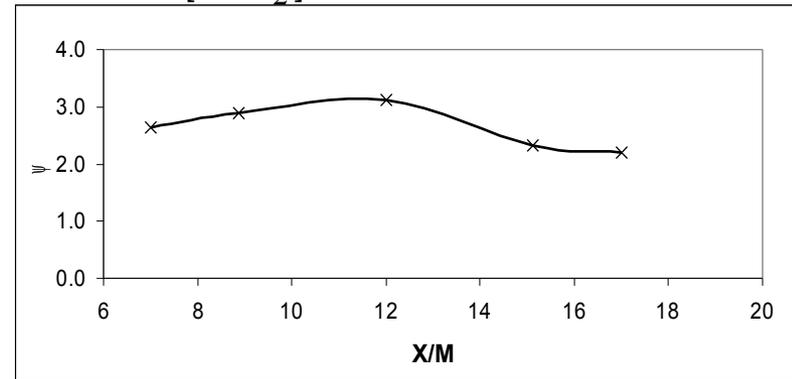

# Preliminary qualitative comparison: results

## NO trend along plume centre line

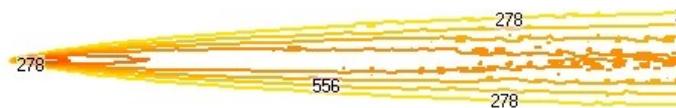

$$\psi = \frac{k[NO][O_3]}{J[NO_2]} \quad k=0.44 \text{ min}^{-1}$$

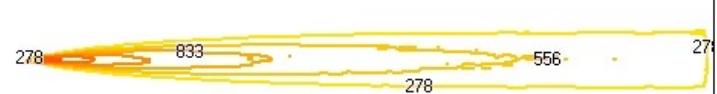

$$J=30 \text{ min}^{-1}$$

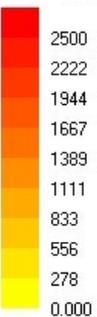

## NO<sub>2</sub> plume, no photolysis, J=0

## NO<sub>2</sub> plume, J=30 min<sup>-1</sup>

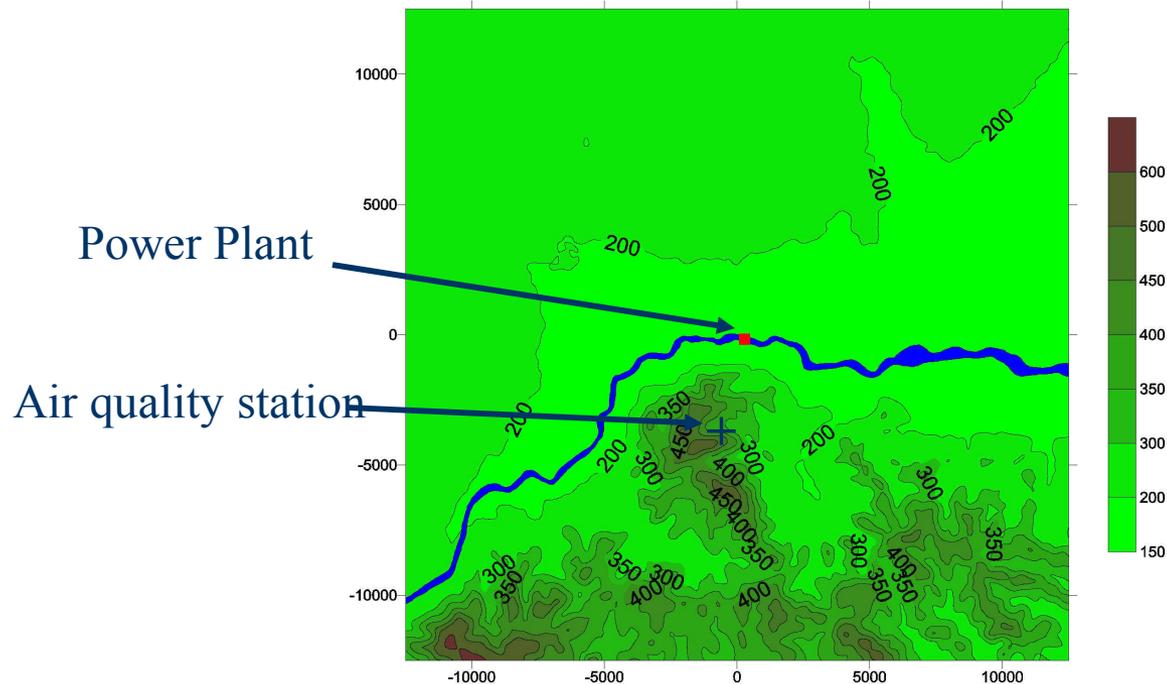

NO<sub>2</sub> (μg m<sup>-3</sup>)

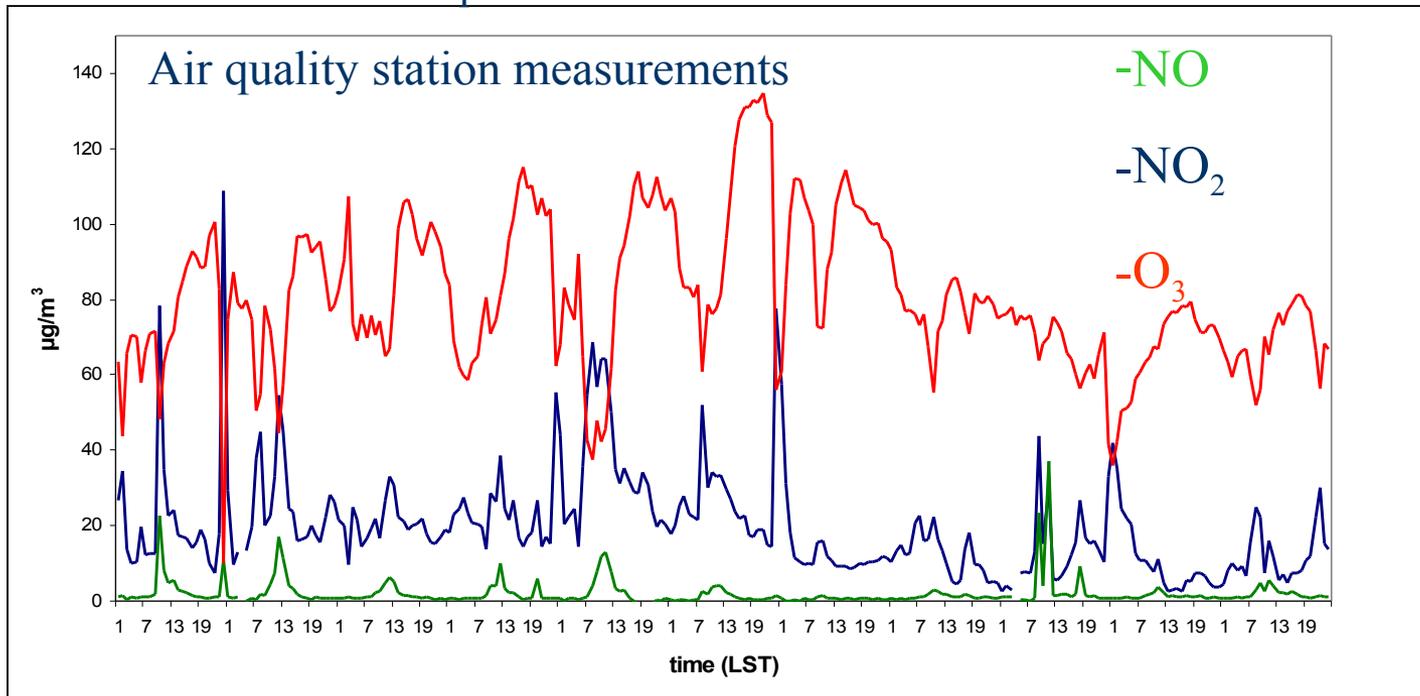

# Real case application: topography and power plant position

- ◆ the station is located in a rural area surrounded by a small village in the south, located on a hill 300 m higher than and 3 km far from the power plant
- ◆ the power plant  $\text{NO}_x$  contribution is isolated from the others, with Northerly, North-Eastelry wind

# Real case application: measured concentration

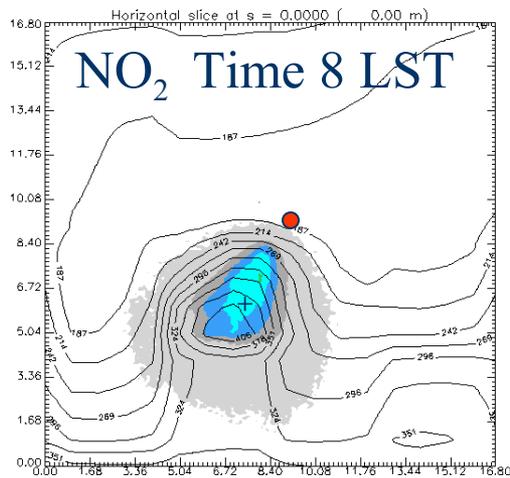

- ◆ A period lasting 10 days, from the 12<sup>th</sup> to 22<sup>th</sup> of March 2007, has been chosen because several plume transits over the station, usually between 6 and 11 LST, were observed and, in general, clear sky and high-pressure conditions occur.
- ◆ The background O<sub>3</sub> concentration for the simulation has been evaluated by the measurements before the plume transit

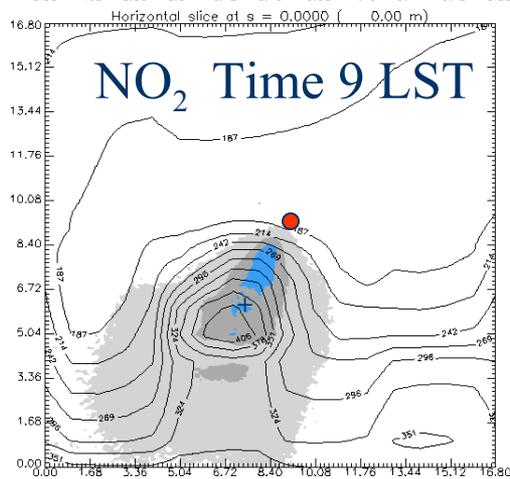

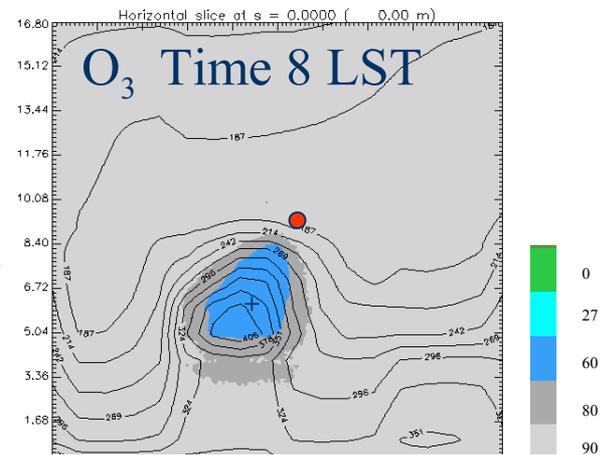

# Real case application: numerical simulation

- ◆ The wind and turbulence fields have been built by the model system RAMS 6.0-MIRS, using the ECMWF analysis fields as boundary conditions
- ◆ 4-d var data assimilation with the meteorological measurements of two ground stations located close to the power plant and the air quality gauges.
- ◆ Three nested grids have been used with a grid spacing of 12, 4 and 1 km respectively; dispersion domain: inner grid is 17x17 km<sup>2</sup>
- ◆ A variable time step for the lagrangian particles displacement; constant time step (20 s) for the chemical reactions.
- ◆ The cells for the concentrations computation have been set equal to 100 x 100 x 50 m<sup>3</sup> and constant all over the domain.

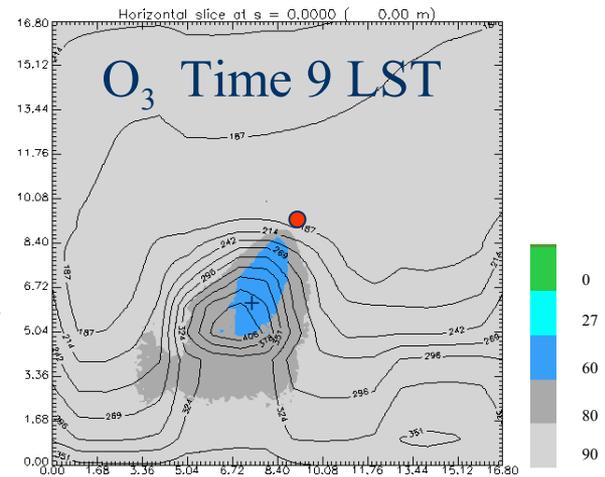

# Concentration field: an example

$J=0.07 \text{ min}^{-1}$   
 $k=0.38 \text{ ppm}^{-1} \text{ sec}^{-1}$

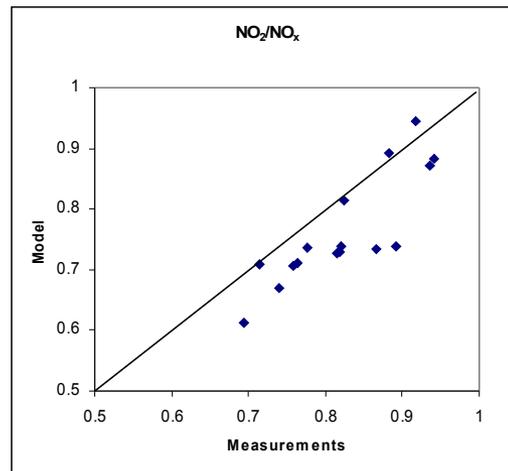

$J=0.22 \text{ min}^{-1}$   
 $k=0.38 \text{ ppm}^{-1} \text{ sec}^{-1}$

# Real case application: comparison with the measurements

- ◆  $\text{NO}_2/\text{NO}_x$  hourly computed ratios are compared with the measurements considering only the diurnal significant situations in order to highlight the chemical scheme performances.
- ◆ Only the Northerly and North-Easterly wind have been chosen to consider only the episodes caused by the plume transits (16 hours) over the gauge

	Mean	Sigma	Bias	Nmse	Cor	Fa2	FB	fas
<b>Measurements</b>	0.82	0.076	0	0	1	1	0	0
<b>Spray</b>	0.76	0.088	-0.059	0.0091	0.85	1.0	0.075	-0.15

# Real case application: comparison with the measurements

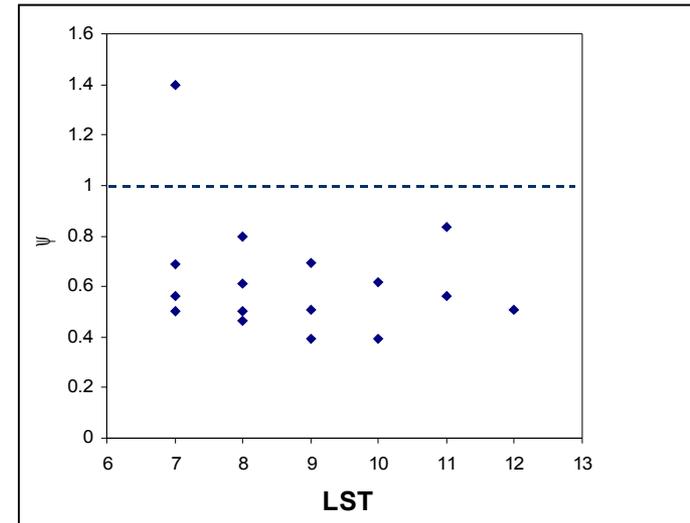

- ◆ The values of  $\psi = \frac{k[NO][O_3]}{J[NO_2]}$  should be  $\geq 1$  inside a plume (Hegg et al. 1977)
- ◆ In this case, considering that the ground station is far from the emission, values of  $\Psi \cong 1$  should be expected
- ◆ In the figure are presented the values of  $\psi$  computed by the measured concentrations and with  $k$  and  $j$  used in the simulation from (IUPAC 2005 and Parrish et al. 1983) assuming clear sky conditions:

$$k = 3.1 \cdot 10^3 \cdot \exp(-1450/T)$$

where  $T$  is the air temperature from RAMS

$$J = 0.01305 \cdot \exp(-0.36/\cos(\alpha))$$

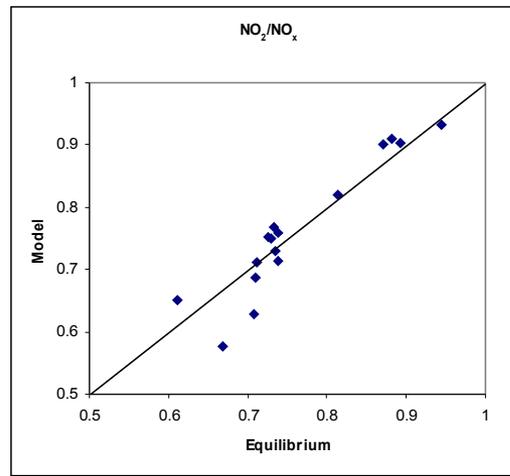

where  $\alpha$  is the complementary of the solar elevation angle

# Real case application: comparison with the photo-stationary equilibrium

- ◆ Model results are also compared with the  $\text{NO}_2/\text{NO}_x$  of the photo-stationary equilibrium, where  $\psi=1$ , at the station location
- ◆ Following Seinfeld (1986), the  $\text{NO}_2/\text{NO}_x$  equilibrium values were computed using the  $\text{NO}_x$  concentrations by Spray and the background  $\text{O}_3$  value

	Mean	Sigma	Bias	Nmse	Cor	Fa2	FB	fas
<b>Equilibrium</b>	0.76	0.10	0	0	1	1	0	0
<b>Spray</b>	0.76	0.088	0.0011	0.0024	0.94	1.0	-0.0014	0.16

# Conclusions

- ◆ A new lagrangian model including the main chemical reaction involving  $\text{NO}_x$  and  $\text{O}_3$  has been developed
- ◆ The mean concentration are calculated on an eulerian grid
- ◆ The  $\text{O}_3$  background concentration are computed through “deficit”
- ◆ The qualitative comparison with wind tunnel data gives reasonable results
- ◆ Real case data comparison shows a general agreement although a slight  $\text{NO}_2/\text{NO}_x$  under estimation occurs due to the lack of cloud cover information
- ◆ The model correctly predict  $\text{NO}_2/\text{NO}_x$  equilibrium concentration even if is able to reproduce non-equilibrium condition

# SPRAY simulation characteristic

- Source dimension (x,y,z): 0.01x0.03x0.03 m<sup>3</sup>;
- NO concentration at the source : 505 p.p.m.;
- Background O<sub>3</sub> concentration: 1 p.p.m.;
- Reaction rate k: 0.44 (s p.p.m.)<sup>-1</sup>, j=30 min<sup>-1</sup> ;
- Time step: 0.1 s;
- Number of emitted particles every time step: 1000 for NO ;
- Boundary conditions at the top and bottom boundaries: Total reflection;
- Number of iterations: 5000
- Concentration grid dimensions (DX, DY, DZ): 0.1, 0.02, 0.02 m
- Average concentrations computed between the time steps 2000 and 5000, saving the temporary concentrations every 50 time steps

# Lagrangian model description

- ◆ SPRAY (Ferrero and Anfossi, 1998) is a Lagrangian stochastic particle model for complex terrain based on three Langevin equations for the random velocities (Thomson, 1987):

$$\begin{aligned} du &= a(x, u)dt + b(x, u)dW(t) \\ dx &= (U + u)dt \end{aligned}$$

**U is the mean wind velocity,**

$$a(x, u)dt$$

**is a deterministic term depending on  $P_E(x, u)$ ,**

$$b(x, u)dW(t)$$

**is a stochastic term**

$$dW(t)$$

**is the incremental Wiener process.**

- ◆ The PDF is assumed to be Gaussian for  $u, v$ , and non-gaussian for  $w$

# Concentration computations

- ◆ The concentration are computed in an Eulerian Grid
- ◆ Concentration in the cell of volume  $V_j$ , is computed considering the total mass of the particles contained

$$\langle c(x_j, t) \rangle = \frac{1}{V_j} \sum_{m=1}^M \int_{\Gamma_j} Q \delta(x' - X^{(m)}(t)) dx'$$
